*Curate, visualize, annotate, and share your behavioral ephys data using Python*

**Distributions**

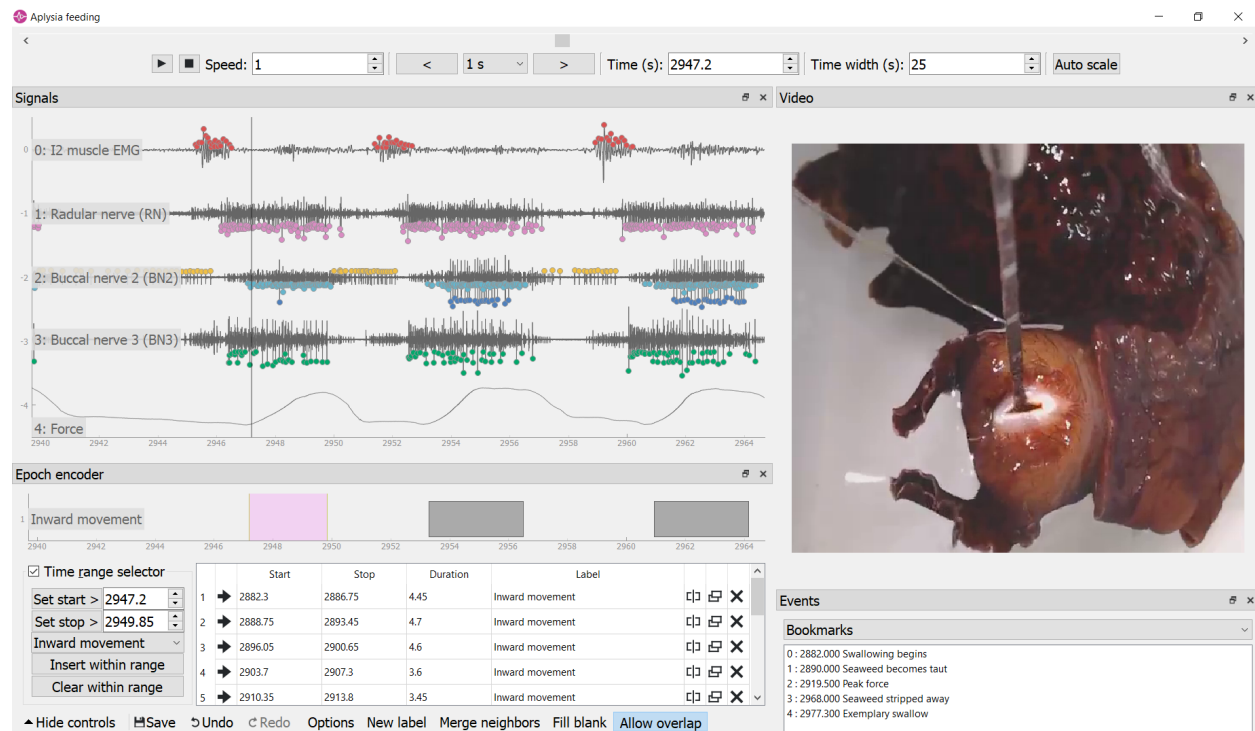

**Source Code**

**Tests Status**

**Citing**

**Version:** 1.5.1.dev0+git.32d131e ([other versions](#))

*neurotic* is an app for Windows, macOS, and Linux that allows you to easily review and annotate your electrophysiology data and simultaneously captured video. It is an easy way to load your [Neo-compatible](#) data (see [neo.io](#) for file formats) into [ephyviewer](#) without doing any programming. Share a single metadata file with your colleagues and they too will quickly be looking at the same datasets!

## 1.1 Overview

To use *neurotic*, first organize your datasets in a *metadata file* like this (see *Configuring Metadata*):

```
my favorite dataset:
  description: This time it actually worked!

  data_dir:      C:\local_dir_containing_files
  remote_data_dir: http://myserver/remote_dir_containing_downloadable_files #
↪ optional
  data_file:      data.axgx
  video_file:     video.mp4
  # etc

  video_offset: -3.4 # seconds between start of video and data acq
  epoch_encoder_possible_labels:
    - label01
    - label02
  plots:
    - channel: I2
      ylim: [-30, 30]
    - channel: RN
      ylim: [-60, 60]
    # etc

  filters: # used only if fast loading is off (lazy=False)
    - channel: Force
      lowpass: 50
    # etc

  amplitude_discriminators: # used only if fast loading is off (lazy=False)
    - name: B3 neuron
      channel: BN2
      units: uV
```

(continues on next page)

(continued from previous page)

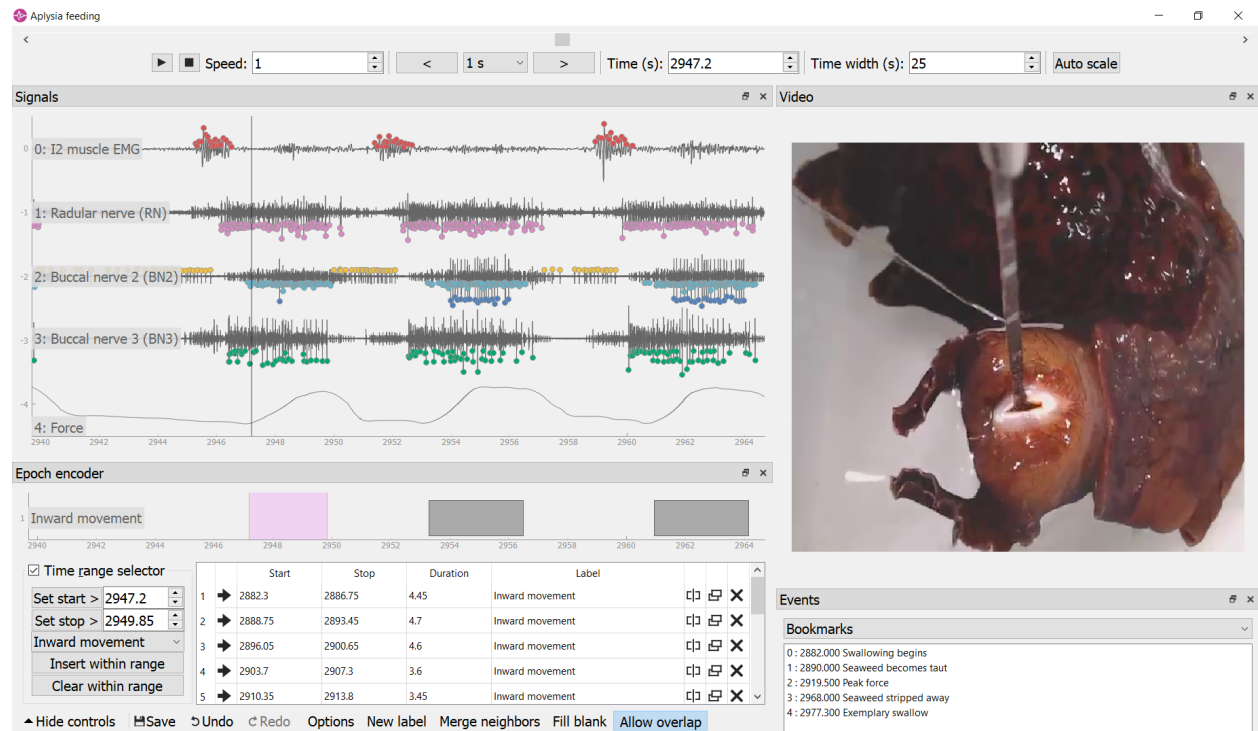

```

amplitude: [50, 100]
# etc

another dataset:
# etc

```

Open your metadata file in *neurotic* and choose a dataset. If the data and video files aren't already on your local computer, the app can download them for you, even from a password-protected server or from Google Drive. Finally, click launch and the app will use a standard viewer layout to display your data to you using *ephyviewer*.

In the screenshot above, the video frame shows a voracious sea slug (*Aplysia californica*) swallowing a strip of unbreakable seaweed attached to a force transducer. Implanted electrodes recorded from a muscle and the major nerves controlling feeding. The epoch encoder was used to mark the times when seaweed moved into the mouth. Spikes corresponding to activity of identified neurons were detected by *neurotic* using customizable parameters.

The viewers are easy and intuitive to navigate (see [User Interface](#)):

- Pressing the play button will scroll through your data and video in real time, or at a higher or lower rate if the speed parameter is changed.
- The arrow/WASD keys allow you to step through time in variable increments.
- Jump to a time by clicking on an event in the event list or a table entry in the epoch encoder.
- To show more or less time at once, right-click and drag right or left to contract or expand time.
- Scroll the mouse wheel in the trace viewer or video viewer to zoom.
- The epoch encoder can be used to block out periods of time during which something interesting is happening for later review or further analysis (saved to a CSV file).
- All panels can be hidden, undocked, stacked, or repositioned on the fly.

Electrophysiologists will find this tool useful even if they don't need the video synchronization feature!

**Portability is easy with neurotic!** Use relative paths in your metadata file along with a remotely accessible data store such as [GIN](#) or a Shared Drive on Google Drive to make your metadata file fully portable. The same metadata file can be copied to a different computer, and downloaded files will automatically be saved to the right place. Data stores can be password protected and *neurotic* will prompt you for a user name and password. This makes it easy to share the *neurotic* experience with your colleagues!

## 1.2 Installing *neurotic*

*neurotic* requires Python 3.7 or later.

### 1.2.1 Standalone Installers (recommended for beginners)

Downloadable installers make installing *neurotic* easy for beginners. They can be downloaded from the [GitHub Releases](#) page:

[Download installers here](#) (listed under “Assets”)

These installers are intended for users who do not want to independently install Python or conda just to use *neurotic*. They will install *neurotic* and everything it needs (including a fully contained Python environment) into a dedicated directory on your computer. On Windows, the installer will also create a Start Menu shortcut for launching the app.

For developers, a recipe for building new installers using [conda constructor](#) is maintained here: [constructor recipe](#).

### 1.2.2 Alternate Method: conda (recommended for Pythonistas)

[conda](#) users can install *neurotic* and all of its dependencies with one command:

```
conda install -c conda-forge neurotic
```

On Windows, this will also create a Start Menu shortcut for launching the app.

### 1.2.3 Alternate Method: pip

Install *neurotic* from [PyPI](#) using

```
pip install neurotic
```

Note that installation via `pip` skips one dependency: [PyAV](#), which is required for displaying videos, and without which *neurotic* will ignore videos. PyAV is not easily installed with `pip` on some systems, especially Windows. The easiest way to separately install PyAV is using [conda](#):

```
conda install -c conda-forge av
```

## 1.3 Updating *neurotic*

The recommended method of updating *neurotic* depends on the original method of installation.

If you are unsure what method you used, updating using `conda` or `pip` is likely to work. Standalone installers may be safe too, though this could lead to having multiple version installed simultaneously.

### 1.3.1 Updating with Standalone Installers

If you previously installed *neurotic* using a standalone installer, you may install a newer version using another installer, either into a different directory or by first uninstalling the old version. Installers can be downloaded from the [GitHub Releases](#) page:

[Download installers here](#) (listed under “Assets”)

Alternatively, if a new installer is not currently available for your platform, or if you would just like a much faster method, you may use the command line tools provided by the installer (via the “Anaconda Prompt” on Windows, or the Terminal on macOS and Linux):

```
conda update -c conda-forge neurotic
```

### 1.3.2 Updating with conda

If you installed *neurotic* with [conda](#), you can update to the latest release using

```
conda update -c conda-forge neurotic
```

### 1.3.3 Updating with pip

If you installed *neurotic* using [pip](#), you can update to the latest release available on [PyPI](#) using

```
pip install -U neurotic
```

### 1.3.4 Development Version

If you are interested in trying new, unreleased features of *neurotic*, you may install the latest development version from [GitHub](#) using

```
pip install -U git+https://github.com/jpgill86/neurotic.git
```

Note that if you install the development version, you may also need the latest development version of [ephyviewer](#), which you can get using

```
pip install -U git+https://github.com/NeuralEnsemble/ephyviewer.git
```

## 1.4 Getting Started

Windows users who installed using a standalone installer or [conda](#) should be able to launch *neurotic* from the Start Menu.

Mac and Linux users, as well as Windows users, can use the Terminal, command line, or Anaconda Prompt to start the app:

1. Depending on your operating system, installation method, and environment settings, you may be able to just launch the app from the command line by invoking its name:

```
neurotic
```

2. If the command is not recognized, you likely need to first activate the conda environment into which the app was installed:

```
conda activate <environment name>
```

If you used a standalone installer, the environment name may be “neurotic”, so you would use

```
conda activate neurotic
```

You can then try again invoking the app name:

```
neurotic
```

Several examples are provided. Select one, download the associated data using the “Download data” menu action, and then click “Launch”. See [User Interface](#) for help with navigation.

Disabling “Fast loading” before launch will enable additional features including amplitude-threshold spike detection and signal filtering.

To inspect the metadata file associated with the examples or to make changes to it, click “Edit metadata”. See [Configuring Metadata](#) for details about the format.

If you like working with Jupyter notebooks, you can launch an example notebook that includes a tutorial for using *neurotic*’s API:

```
neurotic --launch-example-notebook
```

The command line interface accepts other arguments too:

```
usage: neurotic [-h] [-V] [--debug | --no-debug] [--lazy | --no-lazy]
               [--thick-traces | --no-thick-traces]
               [--show-datetime | --no-show-datetime]
               [--ui-scale {tiny,small,medium,large,huge}]
               [--theme {light,dark,original,printer-friendly}]
               [--use-factory-defaults] [--launch-example-notebook]
               [file] [dataset]

neurotic lets you curate, visualize, annotate, and share your behavioral ephys
data.

positional arguments:
  file                  the path to a metadata YAML file (default: an example
                        file)
  dataset              the name of a dataset in the metadata file to select
                        initially (default: the first entry in the metadata
                        file)

optional arguments:
  -h, --help            show this help message and exit
  -V, --version         show program's version number and exit
  --debug               enable detailed log messages for debugging
  --no-debug            disable detailed log messages for debugging (default)
  --lazy                enable fast loading (default)
  --no-lazy             disable fast loading
  --thick-traces        enable support for traces with thick lines, which has
                        a performance cost
  --no-thick-traces     disable support for traces with thick lines (default)
  --show-datetime       display the real-world date and time, which may be
```

(continues on next page)

(continued from previous page)

```
inaccurate depending on file type and acquisition
software
--no-show-datetime do not display the real-world date and time (default)
--ui-scale {tiny,small,medium,large,huge}
                the scale of user interface elements, such as text
                (default: medium)
--theme {light,dark,original,printer-friendly}
        a color theme for the GUI (default: light)
--use-factory-defaults
        start with "factory default" settings, ignoring other
        args and your global config file

alternative modes:
--launch-example-notebook
        launch Jupyter with an example notebook instead of
        starting the standalone app (other args will be
        ignored)

Defaults for arguments and options can be changed in a global config file,
.neurotic/neurotic-config.txt, located in your home directory.
```

## 1.5 Citing *neurotic*

To cite *neurotic* in your publication, please refer to:

Gill, J. P., Garcia, S., Ting, L. H., Wu, M., & Chiel, H. J. (2020). *neurotic*: Neuroscience Tool for Interactive Characterization. eNeuro, 7(3). <https://doi.org/10.1523/ENEURO.0085-20.2020>

Specific versions of the software can be cited from archives at [Zenodo](#).

## 1.6 Configuring Metadata

To load your data with *neurotic*, you must organize them in one or more YAML files, called *metadata files*.

YAML files are very sensitive to punctuation and indentation, so mind those details carefully! Importantly, the tab character cannot be used for indentation; use spaces instead. There are [many free websites](#) that can validate YAML for you.

You may include comments in your metadata file, which should begin with #.

### 1.6.1 Top-Level Organization

Datasets listed within the same metadata file must be given unique names, which may include spaces. The special name `neurotic_config` is reserved for *neurotic* configuration settings and cannot be used for datasets.

In addition to names, a long description can be provided for each dataset.

Details pertaining to each dataset, including the description, are nested beneath the dataset name using indentation. You may need to use double quotes around names, descriptions, or other text if they contain special characters (such as : or #) or are composed only of numbers (such as a date).

```

experiment 2020-01-01:
  description: Both the name and description will be visible when neurotic loads_
  ↳the metadata
    # other details about this dataset will go here

my favorite dataset:
  description: This time it actually worked!
    # other details about this dataset will go here

```

## 1.6.2 Specifying Data Locations

Within a dataset’s YAML block, paths to data and video files should be provided.

All files associated with a dataset should be collected into a single directory. A path to the local copy of this directory can be provided using the `data_dir` key. You may specify `data_dir` as an absolute path (e.g., `C:\Users\me\folder`) or as a path relative to the metadata file (e.g., `folder`). If left unspecified, the directory containing the metadata file is used.

Paths to individual files within the dataset are provided using keys listed below. These paths should be given relative to `data_dir`. If `data_dir` is flat (no subdirectories), these should be simply the file names.

Key	Description
<code>data_file</code>	A single <a href="#">Neo</a> -compatible data file (see <a href="#">neo.io</a> for file formats)
<code>video_file</code>	A video file that can be synchronized with <code>data_file</code>
<code>annotations_file</code>	A CSV file for read-only annotations
<code>epoch_encoder_file</code>	A CSV file for annotations writable by the epoch encoder
<code>tridesclous_file</code>	A CSV file output by <a href="#">tridesclous</a> ’s <code>DataIO.export_spikes</code>

Note that the `annotations_file` must contain exactly 4 columns with these headers: “Start (s)”, “End (s)”, “Type”, and “Label”.

The `epoch_encoder_file` must contain exactly 3 columns with these headers: “Start (s)”, “End (s)”, and “Type”. (The fourth column is missing because ephyviewer’s epoch encoder is currently unable to attach notes to individual epochs; this may be improved upon in the future.)

The `tridesclous_file` is described in more detail in [tridesclous Spike Sorting Results](#).

## 1.6.3 Remote Data Available for Download

Data files must be stored on the local computer for *neurotic* to load them and display their contents. If the files are available for download from a remote server (e.g., a web site, an FTP server, or Google Drive), *neurotic* can be configured to download them for you to the local directory specified by `data_dir` if the files aren’t there already.

Specify the URL to the directory containing the data on the remote server using `remote_data_dir`. *neurotic* expects the local `data_dir` and the `remote_data_dir` to have the same structure and will mirror the `remote_data_dir` in the local `data_dir` when you download data (not a complete mirror, just the specified files).

For an example, consider the following:

```

my favorite dataset:
  data_dir:          C:\Users\me\folder
  remote_data_dir:   http://myserver/remote_folder

```

(continues on next page)

(continued from previous page)

```
data_file:      data.axgx
video_file:     video.mp4
```

With a metadata file like this, the file paths `data_file` and `video_file` are appended to `remote_data_dir` to obtain the complete URLs for downloading these files, and they will be saved to the local `data_dir`.

If you have many datasets hosted by the same server, you can specify the server URL just once using the special `remote_data_root` key, which should be nested under the reserved name `neurotic_config` outside of any dataset's YAML block. This allows you to provide for each dataset a partial URL to a folder in `remote_data_dir` which is relative to `remote_data_root`. For example:

```
neurotic_config:  # reserved name for global settings
  remote_data_root: http://myserver

my favorite dataset:
  data_dir:        C:\Users\me\folder1
  remote_data_dir: remote_folder1
  data_file:       data.axgx
  video_file:      video.mp4

another dataset:
  data_dir:        C:\Users\me\folder2
  remote_data_dir: remote_folder2
  data_file:       data.axgx
  video_file:      video.mp4
```

Here, URLs to video files are composed by joining `remote_data_root` + `remote_data_dir` + `video_file`.

Recall that if `data_dir` is a relative path, it is assumed to be relative to the metadata file. In the example above, if the metadata file is located in `C:\Users\me`, the paths could be abbreviated:

```
neurotic_config:
  remote_data_root: http://myserver

my favorite dataset:
  data_dir:        folder1
  remote_data_dir: remote_folder1
  data_file:       data.axgx
  video_file:      video.mp4

another dataset:
  data_dir:        folder2
  remote_data_dir: remote_folder2
  data_file:       data.axgx
  video_file:      video.mp4
```

---

**Note: Portability is easy with neurotic!** Use relative paths in your metadata file along with a remotely accessible data store such as [GIN](#) or a Shared Drive on Google Drive (see details below) to make your metadata file fully portable. The example above is a simple model of this style. A metadata file like this can be copied to a different computer, and downloaded files will automatically be saved to the right place. Data stores can be password protected and *neurotic* will prompt you for a user name and password. This makes it easy to share the *neurotic* experience with your colleagues!

---

## URLs to Use with Google Drive

After completing some essential manual setup (see *Configuring for Google Drive*), *neurotic* can retrieve remote files from Google Drive using URL-like paths of the following form:

```
gdrive://<drive name>/<folder 1>/<...>/<folder N>/<file name>
```

The `<drive name>` may be “My Drive” for files located in a personal Google Drive, or it may be the name of a Shared Drive that the user has permission to access.

Note that these URL-like paths are not equivalent to ordinary URLs associated with Google Drive files, such as shareable links, which are composed of pseudorandom file IDs and do not reveal anything about the name of the file or the folders containing it. Instead, these URL-like paths allow you to structure your metadata with the file tree hierarchy in mind, so that relative paths can be used.

For example, with datasets stored in subdirectories “datasets/A”, “datasets/B”, etc., of a Shared Drive titled “Lab Project Data”, you could use this metadata to mirror the files locally:

```
neurotic_config:
  remote_data_root:  gdrive://Lab Project Data/datasets

Dataset A:
  data_dir:           A
  remote_data_dir:    A
  data_file:          data.axgx
  video_file:         video.mp4

Dataset B:
  data_dir:           B
  remote_data_dir:    B
  data_file:          data.axgx
  video_file:         video.mp4
```

## URLs to Use with GIN

If you have data stored in a **public** repository on [GIN](#), you can access it from a URL of this form:

```
https://gin.g-node.org/<username>/<reponame>/raw/master/<path>
```

For **private** repositories, you must use a different URL that takes advantage of the WebDAV protocol:

```
https://gin.g-node.org/<username>/<reponame>/_dav/<path>
```

The second form works with public repos too, but GIN login credentials are still required. Consequently, the first form is more convenient for public repos.

## 1.6.4 Global Configuration Settings

The top-level name `neurotic_config` is reserved for configuration settings that apply to all datasets or to the app itself. The following settings may be nested beneath `neurotic_config`.

Key	Description
neurotic_version	A version specification stating the version of <i>neurotic</i> required by the metadata. Presently, if the requirement is not met, only a warning is issued. Quotation marks around the spec are usually required.
remote_data_root	A URL prepended to each <code>remote_data_dir</code> that is not already a full URL (i.e., does not already begin with a protocol scheme like <code>https://</code> )

For example:

```
neurotic_config:
    neurotic_version:  '>=1.4,<2'
    remote_data_root:  http://myserver

my favorite dataset:
    # dataset details here
```

## 1.6.5 Data Reader (Neo) Settings

The electrophysiology file specified by `data_file` is read using *Neo*, which supports many file types. A complete list of the implemented formats can be found here: [neo.io](#).

By default, *neurotic* will use the file extension of `data_file` to guess the file format and choose the appropriate *Neo* IO class for reading it. If the guess fails, you can force *neurotic* to use a different class by specifying the class name with the `io_class` parameter (all available classes are listed here: [neo.io](#)).

Some *Neo* IO classes accept additional arguments beyond just a filename (see the *Neo* docs for details: [neo.io](#)). You can specify these arguments in your metadata using the `io_args` parameter.

For example, suppose you have data stored in a plain text file that is missing a file extension. The `neo.io.AsciiSignalIO` class can read plain text files, but you must specify this manually using `io_class` because the extension is missing. You could do this and pass in supported arguments in the following way:

```
my favorite dataset:
    data_file: plain_text_file_without_file_extension

    io_class: AsciiSignalIO

    io_args:
        skiprows: 1 # skip header
        delimiter: ' ' # space-delimited
        t_start: 5 # sec
        sampling_rate: 1000 # Hz
        units: mV
```

## 1.6.6 Video Synchronization Parameters

### Constant Offset

If data acquisition began with some delay after video capture began, provide a negative value for `video_offset` equal to the delay in seconds. If video capture began after the start of data acquisition, use a positive value. A value of zero will have no effect.

*neurotic* warns users about the risk of async if `video_file` is given but `video_offset` is not. To eliminate this warning for videos that have no delay, provide zero.

## Frame Rate Correction

If the average frame rate reported by the video file is a little fast or slow, you may notice your video and data going out of sync late in a long experiment. You can provide the `video_rate_correction` parameter to fix this. The reported average frame rate of the video file will be multiplied by this factor to obtain a new frame rate used for playback. A value less than 1 will decrease the frame rate and shift video events to later times. A value greater than 1 will increase the frame rate and shift video events to earlier times. A value of 1 has no effect.

You can obtain a good estimate of what value to use by taking the amount of time between two events in the video and dividing by the amount of time between the same two events according to the data record (seen, for example, as synchronization pulses or as movement artifacts).

## Discrete Desynchronization Events

If you paused data acquisition during your experiment while video capture was continuous, you can use the `video_jumps` parameter to correct for these discrete desynchronization events, assuming you have some means of reconstructing the timing. For each pause, provide an ordered pair of numbers in seconds: The first is the time *according to data acquisition* (not according to the video) when the pause occurred, and the second is the duration of the pause during which the video kept rolling.

For example:

```
my favorite dataset:
  video_file: video.mp4
  # etc

  video_jumps:
    # a list of ordered pairs containing:
    # (1) time in seconds when paused occurred according to DAQ
    # (2) duration of pause in seconds
    - [60, 10]
    - [120, 10]
    - [240, 10]
```

These values could correct for three 10-second pauses occurring at times 1:00, 2:00, 3:00 according to the DAQ, which would correspond to times 1:00, 2:10, 3:20 according to the video. The extra video frames captured during the pauses will be excised from playback so that the data and video remain synced.

*neurotic* will automatically suggest values for `video_jumps` if it reads an AxoGraph file that contains stops and restarts (only if `video_jumps` is not already specified).

## 1.6.7 Real-World Date and Time

The GUI can optionally display the real-world date and time. This feature is accurate only if the recording is continuous (no interruptions or pauses during recording) and the start time of the recording is known. Some data file formats may store the start time of the recording, in which case *neurotic* will use that information automatically. However, if the start time is missing or inaccurate, it can be specified in the metadata like this:

```
my favorite dataset:
  data_file: data.axgx
  rec_datetime: 2020-01-01 13:14:15
  # etc
```

### 1.6.8 Plot Parameters

Use the `plots` parameter to specify which signal channels from `data_file` you want plotted and how to scale them. Optionally, a color may be specified for channels using a single letter color code (e.g., 'b' for blue or 'k' for black) or a hexadecimal color code (e.g., '#1b9e77'; note that with PyQtGraph 0.13.0 and later, hexadecimal color codes must begin with #).

Consider the following example, and notice the use of hyphens and indentation for each channel.

```
my favorite dataset:
    data_file: data.axgx
    # etc

    plots:
        - channel: Extracellular
          ylabel: Buccal nerve 2 (BN2)
          units: uV
          ylim: [-150, 150]
          color: r

        - channel: Intracellular
          ylabel: B3 neuron
          units: mV
          ylim: [-100, 50]
          color: '#666666'

        - channel: Force
          units: mN
          ylim: [-10, 500]
```

This would plot the “Extracellular”, “Intracellular”, and “Force” channels from the `data_file` in the given order. `ylabel` is used to relabel a channel and is optional. The `units` and `ylim` parameters are used together to scale each signal such that the given range fits neatly between the traces above and below it. If `units` is not given, they are assumed to be microvolts for voltage signals and millinewtons for force signals. If `ylim` is not given, they default to `[-120, 120]` for voltages and `[-10, 300]` for forces.

If `plots` is not provided, all channels are plotted using the default ranges, except for channels that match these patterns: “Analog Input #\*” and “Clock”. Channels with these names can be plotted if given explicitly by `plots`.

### 1.6.9 Time Range

The amount of time initially visible can be specified in seconds with `t_width`.

The position of the vertical line, which represents the current time in each plot, can be specified as a fraction of the plot range with `past_fraction`. A value of 0 places the vertical line at the left edge of each plot; consequently, everything plotted is “in the future”, occurring after the current time. A value of 1 places the vertical line at the right edge of each plot; consequently, everything plotted is “in the past”, coming before the current time. The default value of 0.3 causes the first 30% of the plot range to display “the past” and the last 70% to display “the future”.

### 1.6.10 Epoch Encoder Parameters

The labels available to the epoch encoder can be specified using `epoch_encoder_possible_labels`. (Additionally, they may be created on the fly using the “New label” button in the epoch encoder.)

For example:

```
my favorite dataset:
  epoch_encoder_file: epoch-encoder.csv
  # etc

  epoch_encoder_possible_labels:
    - label1
    - label2
    - label3
```

### 1.6.11 Filters

Highpass, lowpass, and bandpass filtering can be applied to signals using the `filters` parameter. Note that filters are only applied if fast loading is off (`lazy=False`).

Consider the following example, and notice the use of hyphens and indentation for each filter.

```
my favorite dataset:
  data_file: data.axgx
  # etc

  filters: # used only if fast loading is off (lazy=False)

    - channel: Extracellular
      highpass: 300 # Hz
      lowpass: 500 # Hz

    - channel: Intracellular
      highpass: 300 # Hz

    - channel: Force
      lowpass: 50 # Hz
```

Filter cutoffs are given in hertz. Combining `highpass` and `lowpass` provides bandpass filtering.

### 1.6.12 Amplitude Discriminators

Spikes with peaks (or troughs) that fall within amplitude windows given by `amplitude_discriminators` can be automatically detected by *neurotic* on the basis of amplitude. Note that amplitude discriminators are only applied if fast loading is off (`lazy=False`).

Detected spikes are indicated on the signals with markers, and spike trains are displayed in a raster plot. Optionally, a color may be specified for an amplitude discriminator using a single letter color code (e.g., 'b' for blue or 'k' for black) or a hexadecimal color code (e.g., '#1b9e77'; note that with PyQtGraph 0.13.0 and later, hexadecimal color codes must begin with #).

The algorithm can detect either peaks or troughs in the signal. When both the lower and upper bounds for amplitude windows are positive, the default behavior is to detect peaks. When both are negative, the default is to detect troughs. These defaults can be overridden using `type: trough` or `type: peak`, respectively. This is useful when, for example, detecting subthreshold excitatory postsynaptic potentials. If the signs of the bounds differ, explicit specification of the type is required.

In addition to restricting spike detection for a given unit to an amplitude window, detection can also be limited in time to overlap with epochs with a given label.

Consider the following example, and notice the use of hyphens and indentation for each amplitude discriminator.

```
my favorite dataset:
  data_file: data.axgx
  # etc

  amplitude_discriminators: # used only if fast loading is off (lazy=False)

    - name: Unit 1
      channel: Extracellular
      units: uV
      amplitude: [50, 150]
      color: r

    - name: Unit 2
      channel: Extracellular
      units: uV
      amplitude: [20, 50]
      epoch: Unit 2 activity
      color: '#e6ab02'

    - name: Unit 3
      channel: Intracellular
      units: mV
      amplitude: [-10, 60]
      type: peak
```

Here two units are detected on the “Extracellular” channel with different amplitude windows, and a third unit is detected on the “Intracellular” channel. On the “Extracellular” channel, any peaks between 50 and 150 microvolts will be tagged as a spike belonging to “Unit 1”. The discriminator for “Unit 2” detects smaller peaks, between 20 and 50 microvolts, and it provides the optional `epoch` parameter. This restricts detection of “Unit 2” to spikes within the amplitude window that occur at the same time as epochs labeled “Unit 2 activity”. These epochs can be created by the epoch encoder (reload required to rerun spike detection at launch-time), specified in the read-only `annotations_file`, or even be contained in the `data_file` if the format supports epochs. Finally, peaks between -10 and +60 millivolts will be detected on the “Intracellular” channel; because the signs of these bounds differ, the type (peak or trough) must be explicitly given.

### 1.6.13 tridesclous Spike Sorting Results

`tridesclous` is a sophisticated spike sorting toolkit. The results of a sorting process can be exported to a CSV file using `tridesclous's DataIO.export_spikes` function. This file contains two columns: the first is the sample index of a spike, and the second is the ID for a cluster of spikes. If this file is specified with `tridesclous_file`, then a mapping from the cluster IDs to channels must be provided with `tridesclous_channels`.

In the following example, notice the lack of hyphens:

```
my favorite dataset:
  data_file: data.axgx
  tridesclous_file: spikes.csv
  # etc

  tridesclous_channels:
    0: [Channel A, Channel B]
    1: [Channel A]
    2: [Channel B]
    3: [Channel B]
    # etc
```

Here numeric cluster IDs are paired with a list of channels found in `data_file` on which the spikes were detected.

To show only a subset of clusters or to merge clusters, add the `tridesclous_merge` parameter.

In this example, note again the punctuation:

```
my favorite dataset:
  data_file: data.axgx
  tridesclous_file: spikes.csv
  # etc

  tridesclous_channels:
    0: [Channel A, Channel B]
    1: [Channel A]
    2: [Channel B]
    3: [Channel B]
    # etc

  tridesclous_merge:
    - [0, 1]
    - [3]
```

Now clusters 0 and 1 are combined into a single unit, and only that unit and cluster 3 are plotted; cluster 2 has been discarded.

## 1.6.14 Firing Rates

If spike trains were generated using *Amplitude Discriminators*, imported from *tridesclous Spike Sorting Results*, or included in the `data_file`, their smoothed firing rates can be computed. Note that firing rates are computed only if fast loading is off (`lazy=False`).

Firing rates are plotted as continuous signals. Colors are inherited from `amplitude_discriminators`, if they are provided there.

Firing rates are computed using a kernel that is convolved with the spike train. The metadata is specified like this:

```
my favorite dataset:
  data_file: data.axgx
  # etc

  amplitude_discriminators: # used only if fast loading is off (lazy=False)
    - name: Unit 1
      channel: Extracellular
      units: uV
      amplitude: [50, 150]

  firing_rates: # used only if fast loading is off (lazy=False)
    - name: Unit 1
      kernel: GaussianKernel
      sigma: 1.5 # sec
```

The `elephant` package's `instantaneous_rate` function is used for calculating firing rates. See `elephant.kernels` for the names of kernel classes that may be used with the `kernel` parameter. *neurotic* provides an additional kernel, *CausalAlphaKernel*, which may also be used. The `sigma` parameter is passed as an argument to the kernel class and should be given in seconds.

The rate calculation function and kernel classes are sourced from `neurotic._elephant_tools`, rather than the `elephant` package itself, to avoid requiring `elephant` as a package dependency.

### 1.6.15 Firing Frequency Burst Detectors

If spike trains were generated using *Amplitude Discriminators*, imported from *tridesclous Spike Sorting Results*, or included in the `data_file`, a simple burst detection algorithm that relies on instantaneous firing rate thresholds can be run to detect periods of intense activity. Note that burst detectors are only applied if fast loading is off (`lazy=False`).

Detected bursts are plotted as epochs. Colors are inherited from `amplitude_discriminators`, if they are provided there.

Burst detectors are specified in metadata like this:

```
my favorite dataset:
  data_file: data.axgx
  # etc

  amplitude_discriminators: # used only if fast loading is off (lazy=False)

    - name: Unit 1
      channel: Extracellular
      units: uV
      amplitude: [50, 150]

  burst_detectors: # used only if fast loading is off (lazy=False)

    - spiketrain: Unit 1
      name: Unit 1 burst # optional, used for customizing output epoch name
      thresholds: [10, 8] # Hz
```

The algorithm works by scanning through the spike train with a name matching `spiketrain` (in this example, the spike train generated by the “Unit 1” amplitude discriminator). When the instantaneous firing frequency (IFF; note this is *NOT* the same as the *smoothed firing rate*, but rather the inverse of the inter-spike interval) exceeds the first threshold given (e.g., 10 Hz), a burst of activity is determined to start. After this, at the first moment when the IFF drops below the second threshold (e.g., 8 Hz), the burst is determined to end. After scanning through the entire spike train, many bursts that meet these criteria may be identified.

Note that in general the end threshold should not exceed the start threshold; this would essentially be the same as setting the start and end thresholds both to the greater value.

### 1.6.16 Rectified Area Under the Curve (RAUC)

One way to simplify a high-frequency signal is by plotted a time series of the rectified area under the curve (RAUC). Note that RAUCs are calculated only if fast loading is off (`lazy=False`).

For each signal, the baseline (mean or median) is optionally subtracted off. The signal is then rectified (absolute value) and divided into non-overlapping bins of fixed duration. Finally, the integral is calculated within each bin. The result is a new time series that represents the overall activity of the original signal. RAUC time series are plotted separately from the original signals in a second tab. Colors are inherited from `plots`, if they are provided there.

The choice of baseline is controlled by the `rauc_baseline` metadata parameter, which may have the value `None` (default), `'mean'`, or `'median'`. The size of the bins determines how smooth the RAUC time series is and is set by `rauc_bin_duration`, given in seconds. If `rauc_bin_duration` is not specified (default `None`), RAUC time series will not be calculated.

## 1.7 Metadata Examples

Below, the contents of a fully functioning example metadata file are shown, which contains metadata for several example datasets. This file is included with each installation of *neurotic* and is loaded automatically when *neurotic* first starts.

With this metadata file loaded in *neurotic*, you may use the “Download data” feature to fetch the data files and run the examples, and you may try the “Edit metadata” feature to test modifications (remember to “Reload metadata” after saving changes).

## 1.8 Configuring for Google Drive

*neurotic* can download files from Google Drive (see [URLs to Use with Google Drive](#) for details on how to specify remote URLs). **However, before this capability can be used, you must complete these manual configuration procedures.**

### 1.8.1 Generating a Client Secret File

Because of limitations stated in Google’s Terms of Service on what client-identifying credentials may be included with open source desktop applications, it is not possible for *neurotic* to supply users with an essential file needed for Google Drive access<sup>1</sup>. This file is called the client secret file, and you will need to generate one yourself. The instructions in this section will walk you through this one-time process. This is a normal part of setting up [PyDrive2](#), the library *neurotic* uses for this feature<sup>2</sup>.

The file produced by following these steps, `client_secret.json`, does not provide access to your Google account, so your account is not compromised if the file falls into the “wrong hands”. However, it does identify you to

<sup>1</sup> See [this StackOverflow question](#) for an informal discussion.

<sup>2</sup> See also [PyDrive2 Getting Started](#).

Google as the creator of that file whenever *neurotic* uses it to download files; for this reason, you are discouraged from distributing this file to others, as abuse of it could cause Google to invalidate it and sanction your account.

Follow these steps to create your client secret file:

1. Visit the Google Cloud Platform project dashboard:

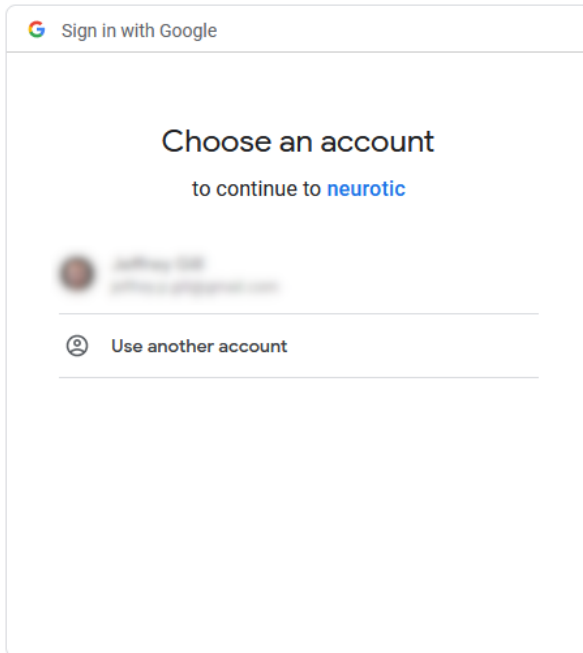

<https://console.cloud.google.com/projectselector2>

2. Click the “Create Project” button, and name the new project “neurotic”, or something similar (the exact name does not matter). Note that you can delete unwanted projects later from the [Cloud Resource Manager](#).
3. Once created, you will be taken to a “Getting Started” page for the new project. The project name should appear at the top of the page, indicating the correct project is selected.
4. Using the search bar at the top of the page, search for and then navigate to “Google Drive API”. On that page, click the “Enable” button.
5. Using the search bar at the top of the page, search for and then navigate to “OAuth consent screen”. Complete the form to configure the consent screen that will be displayed when authorizing *neurotic* to access your Google Drive. The following settings are recommended. Understand that from Google’s perspective you are the developer of the application which will access Google Drive.
  - User type: External
  - App name: “neurotic”
  - User support email: <your email>
  - Developer contact information: <your email>
  - Other optional fields may be left blank
  - Scopes: Search for and add “drive.readonly”
  - Test users: Add email addresses for all Google Drive accounts you would like to use with *neurotic*, including the Google account you are using to make this project if so desired
6. Using the search bar at the top of the page, search for and then navigate to “Credentials”. Click the “Create Credentials” button and choose “OAuth client ID” from the menu. Set Application Type to “Desktop app”. Use the name “Desktop client 1”.
7. After the OAuth client credentials are created, you will see an entry on the Credentials page named “Desktop client 1”. Click the download button on the far right of the entry to download a JSON file. It will have a name like `client_secret_XXX.apps.googleusercontent.com.json`, where XXX is a long random string.
8. Rename the downloaded file to `client_secret.json`.
9. Launch *neurotic*. Under the Help menu, click “Open Google Drive credentials directory”. Move the `client_secret.json` file into this folder.

## 1.8.2 Authorizing *neurotic* to Access Google Drive

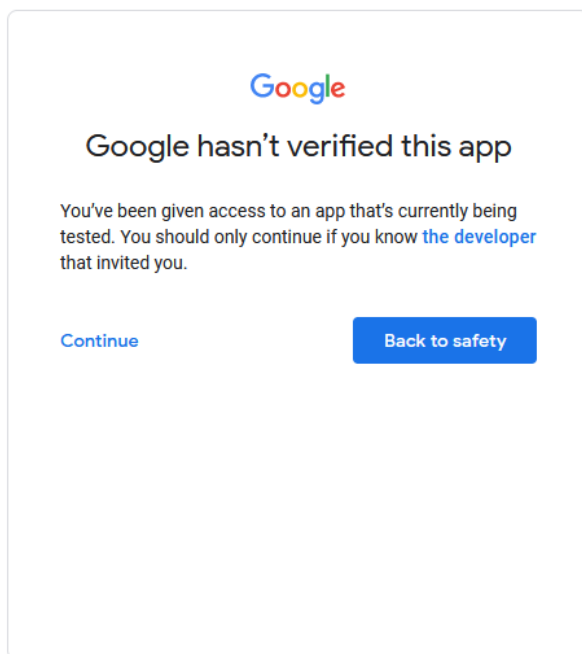

After you have created a client secret file and saved it to the right location, you can attempt to download files from Google Drive using a properly configured metadata file (see [URLs to Use with Google Drive](#) for details). When you do this for the first time, or when you use the “Request Google Drive authorization now” action under the Help menu, you will need to complete the following steps to authorize *neurotic* to access your Google Drive:

1. Your web browser will open and ask you to sign into a Google account before continuing to *neurotic*. You will need to select one of your Google accounts that was added as a “test user” when creating the client secret file. Other accounts will be denied access.

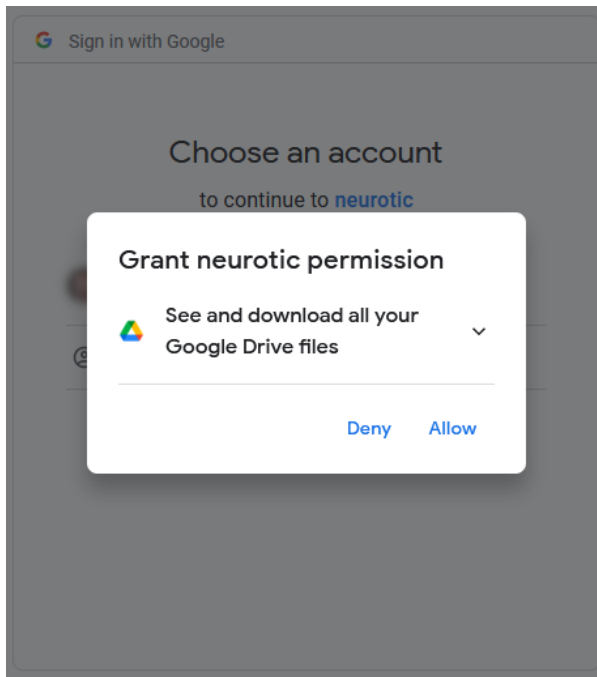

2. Next you will see a notification that the app has not been verified by Google. Your own email address will be listed as the software developer because this notice is associated with the client secret file you created. The message will also state that the app is being tested (rather than is a finalized product) because the project you created for the client secret file is private.

Due to the terms-of-service limitations mentioned earlier, it is not possible for *neurotic* to distribute a client secret file that would avoid presenting you with this notice. This policy exists because open source desktop applications can be modified by anyone with access to the system at any time, making it impossible for Google to certify that the mutable app has any particular identity and is safe. If you trust the application and are willing to proceed, click “Continue”.

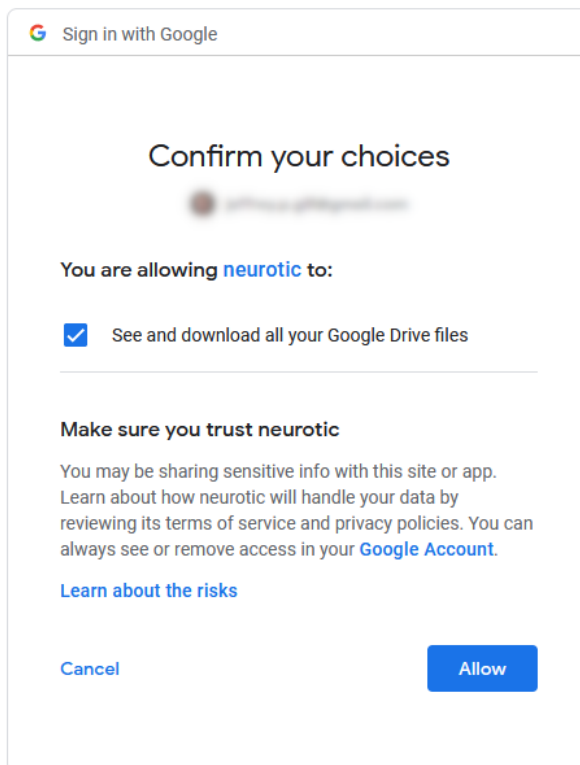

3. To download files from your Google Drive, *neurotic* needs the privileges to access and read those files. Click

“Allow” to indicate that you want to allow this.

4. Click “Allow” another time to confirm.

5. When you see this message in your browser, you can close it: “The authentication flow has completed.”

The authorization process should now be complete, and you can begin using *neurotic* to access and download Google Drive files.

### 1.8.3 Making Google Drive Authorization Persistent

By default, authorization persists only until *neurotic* is closed. Each time *neurotic* is restarted and you want to download from Google Drive again, you will need to repeat the authorization procedure described above. You can avoid this by configuring *neurotic* to retain the products of authorization (access and refresh tokens) indefinitely. See [Changing Default Behavior](#) for details on the global configuration file; by setting the `save_tokens` parameter under the `gdrive` heading to `true`, you can minimize the frequency of authorization requests.

**Warning:** Enabling `save_tokens` is not recommended on systems used by others you do not trust. These others will be able to download files from your Google Drive using *neurotic* with the same level of ease you experience, and with access to the token file they could use it outside of *neurotic* to gain read-only access to your Google Drive and your Shared Drives.

### 1.8.4 Purging Google Drive Authorization

If you need to use a different Google account than the one you previously authorized *neurotic* to use, or if you had set `save_tokens=true` and now want to remove the persistent access and refresh tokens from your system, you can use the “Purge Google Drive authorization token” action from the Help menu. After using this, you will need to complete the authorization procedure again, and you will have the opportunity to select a different Google account.

## 1.9 Changing Default Behavior

Default parameters used by the app and by the command line interface, such as which metadata file to open initially or whether Google Drive access tokens should be stored indefinitely, can be configured using global configuration settings located in `.neurotic/neurotic-config.txt` in your home directory:

- Windows: `C:\Users\<username>\.neurotic\neurotic-config.txt`
- macOS: `/Users/<username>/.neurotic/neurotic-config.txt`
- Linux: `/home/<username>/.neurotic/neurotic-config.txt`

The file can be opened easily using the “View global config file” menu action. You may edit it to customize your settings. The next time you launch the app or use the command line interface, your changes should be in effect.

If this file does not exist when *neurotic* is launched, the following template is created for you:

```
# --- neurotic global config -----
# Use this file to configure the way neurotic behaves. This file uses the TOML
# format.

[defaults]
# When the app is launched, the following customizable defaults are used unless
# overridden by command line arguments. Example uses include:
# - Uncomment the "file" parameter and insert the path to your favorite
#   metadata file so that it always opens automatically
# - Uncomment the "lazy" parameter and set it to false to always disable fast
#   loading, ensuring that expensive procedures like spike detection and
#   filtering are performed by default
# To open the example metadata file by default, either leave the "file"
# parameter unset, set it to false, or set it to "example". To initially select
# the first dataset in the file, either leave the "dataset" parameter unset,
```

(continues on next page)

(continued from previous page)

```
# set it to false, or set it to "first".

# file = false
# dataset = false
# debug = false
# lazy = true
# thick_traces = false
# show_datetime = false
# ui_scale = "medium"
# theme = "light"

[gddrive]
# The "save_tokens" parameter controls how often you need to authorize neurotic
# to access your Google Drive account for downloads:
#   - Set "save_tokens" to true to remember Google Drive access tokens after
#     authorization, so that permissions only need to be granted once. This is
#     not recommended if others you do not trust have access to this computer,
#     as it could let them download files from your Google Drive account.
#   - Set "save_tokens" to false or leave it unset to forget access
#     authorization after neurotic closes. Each time you restart neurotic, you
#     will be required to re-grant permissions when you download a Google Drive
#     file.

# save_tokens = false

[app]
# When the app is launched, neurotic automatically checks for updates unless
# the "auto_check_for_updates" parameter is set to false.

# auto_check_for_updates = true
```

## 1.10 API Reference Guide

In addition to using *neurotic* as a standalone app, you can also leverage its API in your own code.

---

**Note:** **TL;DR:** The easiest way to use *neurotic* in an interactive session or script is by invoking *neurotic.quick\_launch()*. For example:

```
>>> metadata = {'data_file': 'data.axgx'}
>>> neurotic.quick_launch(metadata=metadata)
```

or

```
>>> neurotic.quick_launch(blk=my_neo_block)
```

---

The core of the API consists of two classes and one function:

- *neurotic.datasets.metadata.MetadataSelector*: Read metadata files, download datasets
- *neurotic.datasets.data.load\_dataset()*: Read datasets, apply filters and spike detection
- *neurotic.gui.config.EphyviewerConfigurator*: Launch ephyviewer

All public package contents are automatically imported directly into the `neurotic` namespace. This means that a class like `neurotic.datasets.metadata.MetadataSelector` can be accessed more compactly as `neurotic.MetadataSelector`.

### 1.10.1 `neurotic.datasets.data`

The `neurotic.datasets.data` module implements a function for loading a dataset from selected metadata.

```
neurotic.datasets.data.load_dataset(metadata,          blk=None,          lazy=False,
                                   signal_group_mode='split-all',      fil-
                                   ter_events_from_epochs=False)
```

Load a dataset.

`metadata` may be a `MetadataSelector` or a simple dictionary containing the appropriate data.

The `data_file` in `metadata` is read into a `NeoBlock` using an automatically detected `neo.io` class if `lazy=False` or a `neo.rawio` class if `lazy=True`. If `data_file` is unspecified, an empty `NeoBlock` is created instead. If a `NeoBlock` is passed as `blk`, `data_file` is ignored.

Epochs and events loaded from `annotations_file` and `epoch_encoder_file` and spike trains loaded from `tridesclous_file` are added to the `NeoBlock`.

If `lazy=False`, parameters given in `metadata` are used to apply filters to the signals, to detect spikes using amplitude discriminators, to calculate smoothed firing rates from spike trains, to detect bursts of spikes, and to calculate the rectified area under the curve (RAUC) for each signal.

### 1.10.2 `neurotic.datasets.download`

The `neurotic.datasets.download` module implements a general purpose download function that handles connecting to remote servers, performing authentication, and downloading files with progress reporting. The function handles various errors and will automatically reprompt the user for login credentials if a bad user name or password is given.

The module installs an `urllib.request.HTTPBasicAuthHandler` and a `neurotic.datasets.ftpauth.FTPBasicAuthHandler` at import time.

```
neurotic.datasets.download.download(url,          local_file,          overwrite_existing=False,
                                   show_progress=True, bytes_per_chunk=8192)
```

Download a file.

### 1.10.3 `neurotic.datasets.ftpauth`

The `neurotic.datasets.ftpauth` module implements a `urllib.request`-compatible FTP handler that prompts for and remembers passwords.

**class** `neurotic.datasets.ftpauth.FTPBasicAuthHandler` (`password_mgr=None`)

This subclass of `urllib.request.FTPHandler` implements basic authentication management for FTP connections. Like `urllib.request.HTTPBasicAuthHandler`, this handler for FTP connections has a password manager that it checks for login credentials before connecting to a server.

This subclass also ensures that file size is included in the response header, which can fail for some FTP servers if the original `FTPHandler` is used.

This handler can be installed globally in a Python session so that calls to `urllib.request.urlopen('ftp://...')` will use it automatically:

```
>>> handler = FTPBasicAuthHandler()
>>> handler.add_password(None, uri, user, passwd) # realm must be None
>>> opener = urllib.request.build_opener(handler)
>>> urllib.request.install_opener(opener)
```

`neurotic.datasets.ftpauth.setup_ftpauth()`

Install `neurotic.datasets.ftpauth.FTPBasicAuthHandler` as the global default FTP handler.

Note that `urllib.request.install_opener()` used here will remove all other non-default handlers installed in a different opener, such as an `urllib.request.HTTPBasicAuthHandler`.

## 1.10.4 neurotic.datasets.gdrive

The `neurotic.datasets.gdrive` module implements a class for downloading files from Google Drive using paths, rather than file IDs or shareable links.

```
class neurotic.datasets.gdrive.GoogleDriveDownloader(client_secret_file,
                                                    tokens_file=None,
                                                    save_tokens=False)
```

A class for downloading files from Google Drive using paths.

Files can be specified for download using URL-like paths of the form

`gdrive://<drive name>/<folder 1>/<...>/<folder N>/<file name>`

The “<drive name>” may be “My Drive” for files located in a personal Google Drive, or it may be the name of a Shared Drive that the user has permission to access.

Note that these URL-like paths are not equivalent to ordinary URLs associated with Google Drive files, such as shareable links, which are composed of pseudorandom file IDs and do not reveal anything about the name of the file or the folders containing it.

This class can only download files that are uniquely identifiable by their paths. Google Drive does not require file or folder names to be unique, so two or more files or folders with identical names may coexist in a folder. Such files and folders cannot be distinguished by their paths, so they cannot be downloaded using this class. A download will fail while traversing the file tree if at any step there is more than one folder or file that matches the path.

This class manages access authorization, optionally saving authorization tokens to a file so that the authorization flow does not need to be repeated in the future.

The `client_secret_file` should be the path to a client secret file in JSON format, obtained from the [Google API Console](#). The Drive API must be enabled for the corresponding client.

If `save_tokens=False`, the authorization flow (a request via web browser for permission to access Google Drive) will always run the first time a new instance of this class is used, and authorization will not persist after the instance is destroyed. If `save_tokens=True` and a file path is provided with `tokens_file`, access/refresh tokens resulting from a successful authorization are stored in the file, and tokens are loaded from the file in the future, so that the authorization flow does not need to be repeated.

**GetSharedDrivesList()**

Return information about available Shared Drives.

**GetUserEmail()**

Get the email address for the authorized Google Drive account.

**authorize()**

Obtain tokens for reading the contents of a Google Drive account.

If `save_tokens=True`, tokens will be loaded from the `tokens_file` if possible. If tokens cannot be restored this way, or if the loaded tokens have expired, an authorization flow will be initiated, prompting the user through a web browser to grant read-only privileges to the client associated with the `client_secret_file`. When the authorization flow completes, if `save_tokens=True`, the newly created tokens will be stored in the `tokens_file` for future use.

Authorization is performed automatically when needed, but this method can be called directly to retrieve (and possibly store) tokens without initiating a download.

#### **deauthorize()**

Forget tokens and delete the `tokens_file`. The authorization flow will be required for the next download.

#### **download(gdrive\_url, local\_file, overwrite\_existing=False, show\_progress=True, bytes\_per\_chunk=5242880)**

Download a file from Google Drive using a URL-like path beginning with “gdrive://”.

#### **is\_authorized()**

Get the current authorization state.

## 1.10.5 neurotic.datasets.metadata

The `neurotic.datasets.metadata` module implements a class for reading metadata files.

```
class neurotic.datasets.metadata.MetadataSelector(file=None, local_data_root=None,  
                                                remote_data_root=None, initial_selection=None)
```

A class for managing metadata.

A metadata file can be specified at initialization, in which case it is read immediately. The file contents are stored as a dictionary in `all_metadata`.

```
>>> metadata = MetadataSelector(file='metadata.yml')
>>> print(metadata.all_metadata)
```

File contents can be reloaded after they have been changed, or after changing file, using the `load()` method.

```
>>> metadata = MetadataSelector()
>>> metadata.file = 'metadata.yml'
>>> metadata.load()
```

A particular metadata set contained within the file can be selected at initialization with `initial_selection` or later using the `select()` method. After making a selection, the selected metadata set is accessible at `metadata.selected_metadata`, e.g.

```
>>> metadata = MetadataSelector(file='metadata.yml')
>>> metadata.select('Data Set 5')
>>> print(metadata.selected_metadata['data_file'])
```

A compact indexing method is implemented that allows the selected metadata set to be accessed directly, e.g.

```
>>> print(metadata['data_file'])
```

This allows the `MetadataSelector` to be passed to functions expecting a simple dictionary corresponding to a single metadata set, and the selected metadata set will be used automatically.

Files associated with the selected metadata set can be downloaded individually or all together, e.g.

```
>>> metadata.download('video_file')
```

or

```
>>> metadata.download_all_data_files()
```

The absolute path to a local file or the full URL to a remote file associated with the selected metadata set can be resolved with the `abs_path()` and `abs_url()` methods, e.g.

```
>>> print(metadata.abs_path('data_file'))
>>> print(metadata.abs_url('data_file'))
```

**abs\_path** (*file*)

Convert the relative path of *file* to an absolute path using `data_dir`.

**abs\_url** (*file*)

Convert the relative path of *file* to a full URL using `remote_data_dir`.

**all\_metadata** = **None**

A dictionary containing the entire file contents, set by `load()`.

**download** (*file*, **\*\*kwargs**)

Download a file associated with the selected metadata set.

See `neurotic.datasets.download.download()` for possible keyword arguments.

**download\_all\_data\_files** (**\*\*kwargs**)

Download all files associated with the selected metadata set.

See `neurotic.datasets.download.download()` for possible keyword arguments.

**keys**

The available metadata keys.

**load** ()

Read the metadata file.

**select** (*selection*)

Select a metadata set.

**selected\_metadata**

The access point for the selected metadata set.

## 1.10.6 neurotic.gui.config

The `neurotic.gui.config` module implements a class for configuring and launching ephyviewer for a loaded dataset.

**class** `neurotic.gui.config.EphyviewerConfigurator` (*metadata*, *blk*, *lazy=False*)

A class for launching ephyviewer for a dataset with configurable viewers.

At initialization, invalid viewers are automatically disabled (e.g., the video viewer is disabled if `video_file` is not given in `metadata`). Viewers can be hidden or shown before launch using the built-in methods. Valid viewer names are:

- `traces`
- `traces_rauc`
- `freqs`

- `spike_trains`
- `traces_rates`
- `epochs`
- `epoch_encoder`
- `video`
- `event_list`
- `data_frame`

`launch_ephyviewer()` is provided for starting a new Qt app and launching the ephyviewer main window all at once. `create_ephyviewer_window()` generates just the ephyviewer window and should be used if there is already a Qt app running.

**create\_ephyviewer\_window** (*theme*='light', *ui\_scale*='medium', *support\_increased\_line\_width*=False, *show\_datetime*=False, *datetime\_format*='%Y-%m-%d %H:%M:%S')

Load data into each ephyviewer viewer and return the main window.

**disable** (*name*)

Disable the viewer name.

**enable** (*name*)

Enable the viewer name.

**hide** (*name*)

Hide the viewer name.

**hide\_all** ()

Hide all viewers.

**is\_enabled** (*name*)

Return whether the viewer name is enabled.

**is\_shown** (*name*)

Return whether the viewer name is shown.

**launch\_ephyviewer** (*theme*='light', *ui\_scale*='medium', *support\_increased\_line\_width*=False, *show\_datetime*=False, *datetime\_format*='%Y-%m-%d %H:%M:%S')

Start a Qt app and create an ephyviewer window.

**show** (*name*)

Show the viewer name.

**show\_all** ()

Show all viewers.

## 1.10.7 neurotic.gui.epochencoder

The `neurotic.gui.epochencoder` module implements a subclass of `ephyviewer.datasources.epochs.WritableEpochSource`.

**class** `neurotic.gui.epochencoder.NeuroticWritableEpochSource` (*filename*, *possible\_labels*, *color\_labels*=None, *channel\_name*="", *backup*=True)

A subclass of `ephyviewer.datasources.epochs.WritableEpochSource` for custom CSV column formatting and automatic file backup.

### 1.10.8 neurotic.gui.notebook

The `neurotic.gui.notebook` module implements Jupyter notebook widget counterparts for the `MetadataSelector` and the `EphyviewerConfigurator`.

```
class neurotic.gui.notebook.MetadataSelectorWidget (file=None,                                lo-
                                                    cal_data_root=None,          re-
                                                    mote_data_root=None,          ini-
                                                    tial_selection=None)
```

Interactive list box for Jupyter notebooks that allows the user to select which metadata set they would like to work with.

```
>>> metadata = MetadataSelectorWidget (file='metadata.yml')
>>> display(metadata)
```

After clicking on an item in the list, the selected metadata set is accessible at `metadata.selected_metadata`, e.g.

```
>>> metadata.selected_metadata['data_file']
```

A compact indexing method is implemented that allows the selected metadata set to be accessed directly, e.g.

```
>>> metadata['data_file']
```

This allows the `MetadataSelectorWidget` to be passed to functions expecting a simple dictionary corresponding to a single metadata set, and the selected metadata set will be used automatically.

```
class neurotic.gui.notebook.EphyviewerConfiguratorWidget (metadata,                                blk,
                                                         lazy=False)
```

Interactive button grid for Jupyter notebooks that allows the user to select which ephyviewer viewers they would like to display and then launch ephyviewer.

**disable** (name)  
Disable the viewer name.

**enable** (name)  
Enable the viewer name.

**hide** (name)  
Hide the viewer name.

**show** (name)  
Show the viewer name.

### 1.10.9 neurotic.gui.standalone

The `neurotic.gui.standalone` module implements the main window of the app.

```
class neurotic.gui.standalone.MainWindow (file=None,  initial_selection=None,  lazy=True,
                                           theme='light',                                ui_scale='medium',
                                           support_increased_line_width=False,
                                           show_datetime=False)
```

The main window of the app.

### 1.10.10 neurotic.scripts

The `neurotic.scripts` module handles starting the app from the command line. It also provides a convenience function for quickly launching the app using minimal metadata or an existing Neo `Block`, and another for starting a

Jupyter server with an example notebook.

`neurotic.scripts.quick_launch(metadata={}, blk=None, lazy=True)`

Load data, configure the GUI, and launch the app with one convenient function.

This function allows *neurotic* to be used easily in interactive sessions and scripts. For example, dictionaries can be passed as metadata:

```
>>> metadata = {'data_file': 'data.axgx'}
>>> neurotic.quick_launch(metadata=metadata)
```

An existing Neo Block can be passed directly:

```
>>> neurotic.quick_launch(blk=my_neo_block)
```

This function is equivalent to the following:

```
>>> blk = load_dataset(metadata, blk, lazy=lazy)
>>> ephyviewer_config = EphyviewerConfigurator(metadata, blk, lazy=lazy)
>>> ephyviewer_config.show_all()
>>> ephyviewer_config.launch_ephyviewer()
```

`neurotic.scripts.launch_example_notebook()`

Start a Jupyter server and open the example notebook.

### 1.10.11 `neurotic._elephant_tools`

The `neurotic._elephant_tools` module contains functions and classes copied from the `elephant` package, which are included for convenience and to eliminate dependency on that package. Original code that builds on this work (e.g., a new kernel) is also contained in this module.

**Warning:** This module and the functions and classes it contains are not intended to be part of *neurotic*'s public API, so the module name begins with an underscore. This module may be moved, renamed, or removed at a future date and replaced with explicit dependence on the `elephant` package.

**class** `neurotic._elephant_tools.CausalAlphaKernel` (*sigma*, *invert=False*)

This modified version of `elephant.kernels.AlphaKernel` shifts time such that convolution of the kernel with spike trains (as in `elephant.statistics.instantaneous_rate()`) results in alpha functions that begin rising at the spike time, not before. The entire area of the kernel comes after the spike, rather than half before and half after, as with `AlphaKernel`. Consequently, `CausalAlphaKernel` can be used in causal filters.

The equation used for `CausalAlphaKernel` is

$$K(t) = \begin{cases} (1/\tau^2) t \exp(-t/\tau), & t > 0 \\ 0, & t \leq 0 \end{cases}$$

with  $\tau = \sigma/\sqrt{2}$ , where  $\sigma$  is the parameter passed to the class initializer.

In neuroscience a popular application of kernels is in performing smoothing operations via convolution. In this case, the kernel has the properties of a probability density, i.e., it is positive and normalized to one. Popular choices are the rectangular or Gaussian kernels.

Exponential and alpha kernels may also be used to represent the postynaptic current / potentials in a linear (current-based) model.

**sigma** [Quantity scalar] Standard deviation of the kernel.

**invert: bool, optional** If true, asymmetric kernels (e.g., exponential or alpha kernels) are inverted along the time axis. Default: False

## 1.11 Release Notes

### 1.11.1 neurotic 1.5.0

2021-01-17

This release's biggest feature is Google Drive integration: Use *neurotic* to fetch data files from either My Drive or Shared Drives (formerly known as Team Drives). Read more here: [URLs to Use with Google Drive](#) and [Configuring for Google Drive](#).

Additionally, you can now customize some default settings for *neurotic*, such as which metadata file is opened by default. Read more here: [Changing Default Behavior](#).

#### New features

- Add capability to download files from Google Drive (#294, #297, #309)
- Allow users to change defaults in a global configuration file (#285, #304)

#### Improvements

- Automatically check for updates when the app is launched (#307, #310)
- Remove incomplete files when a download is interrupted (#280)
- Add amplitude discriminator parameter for extrema type (detect peaks or troughs) (#284)
- Annotate detected spike trains with amplitude discriminator units and epoch (#281, #282, #284)

#### Documentation

- Many aesthetic and content improvements to the documentation (#256, #268, #269, #272, #273, #274, #275, #295, #298, #302, #303, #305, #306, #308)

#### Testing

- Transition to GitHub Actions for automated testing (#286, #287, #299, #301)
- Add tests for and declare support for Python 3.9 (#283)
- Exclude py files not part of the main package from coverage reports (#300)

### 1.11.2 neurotic 1.4.1

2020-03-15

## Improvements

- Add `neurotic_version` parameter to metadata (#247)
- Revised and added new example datasets (#250, #251)

## Bug fixes

- Fix broken import of Neo's `generate_one_simple_block` in example notebook (#253)
- Fix default font size determination in scripts and Jupyter notebooks (#249)

## Other changes

- Make “large” UI scale larger and “huge” UI scale huger (#244)
- Scale loading message with other fonts (#245)
- Address numpy FutureWarning when epoch list is empty (#248)

## Documentation

- Add project acronym to package description, app, and docs (#252)
- Building of standalone installers is now automated (#254)

## 1.11.3 neurotic 1.4.0

2020-03-04

## New features

- Add computation of smoothed firing rates for spike trains (#189)
- Add `quick_launch` function for easier scripting and interactive sessions (#191, #196)
- Add `blk` param to `load_dataset` for using existing Neo Block (#196)
- Add `rec_datetime` metadata parameter for setting real-world start time (#190)
- Add `past_fraction` metadata parameter for controlling the placement of the vertical line marking the current time (#220)
- Add color options for signal plots to metadata (#177)
- Add options for scaling the user interface (#222, #241, #242)
- Add launch via double click in standalone app (#218)

## Help & feedback

- Display loading indicator when launching in the standalone app (#223)
- Prompt the user to reload metadata after using the menu to edit metadata (#226)
- Show “Downloads complete” in app status bar and in log (#219)

- Add menu action status tips to standalone app (#221, #240)
- Add “Check for updates” to help menu (#201)
- Add Help menu actions for opening common URLs (#198, #230)
- Add Python version and *neurotic* install path to About window (#181)
- Display common error messages to status bar in standalone app (#225)
- Display a splash screen when first starting the standalone app (#224)

## Jupyter tutorial

Start the tutorial using `neurotic --launch-example-notebook` or [view it here](#).

- Add API tutorial to example Jupyter notebook (#234, #236)
- Add shell commands to example Jupyter notebook for installing *neurotic* (#185)

## Other changes

- Move RAUC calculations to `load_dataset` and store them as annotations (#188)
- Disable RAUC calculations by default (#193)
- Allow `data_file` to be unspecified in metadata and signals to be optional (#195)
- Ignore `video_file` if PyAV is not installed (#231)
- Rename elephant functions (#183)

## Bug fixes

- Fix crash when `plots` list is empty (#217)
- Fix plotted signal sampling rate and start time if units are not Hz and sec, respectively (#194)
- Fix incompatibility with old versions of `tqdm` and unknown download size (#184)

## Documentation

- Improve installation and updating documentation (#180, #229)

## Logging

- Add package logger and permanent log file (#174)
- Log fatal errors in standalone app instead of crashing (#176)
- Add CLI and GUI options for enabling debug log messages (#178)
- Raise the default threshold for PyAV messages from warning to critical (#179)

## 1.11.4 neurotic 1.3.0

2020-01-07

## Improvements

- Add burst detection via firing rate thresholding (#156)
- Add button for auto-scaling signals to main window (#150)
- Add metadata color parameters for `amplitude_discriminators` (#166)
- Add metadata parameters `rauc_baseline` and `rauc_bin_duration` (#151)
- Make `data_dir` default to metadata file directory (#163)

## Bug fixes

- Unmask `FileNotFoundError` when local data file is missing (#154)

## Documentation

- Add Zenodo archive badge (#162)

### 1.11.5 neurotic 1.2.1

2019-12-09

#### Bug fixes

- Fix loading using Neo IOs lacking `signals_group_mode` (`TypeError: read_block() got an unexpected keyword argument 'signal_group_mode'`) (#143)

### 1.11.6 neurotic 1.2.0

2019-12-06

*neurotic* should now have broader compatibility with file types supported by Neo's `neo.io` classes thanks to two new metadata parameters: `io_class` and `io_args`. See *Data Reader (Neo) Settings* for details.

*neurotic* is now available on conda-forge! See *Alternate Method: conda (recommended for Pythonistas)* for details on how to install.

## Improvements

- Add metadata parameters `io_class` and `io_args` (#137)

## Documentation

- Add conda-forge installation instructions (#128)

### 1.11.7 neurotic 1.1.1

2019-10-17

## Changes

- Remove elephant as a dependency (#120)

### 1.11.8 neurotic 1.1.0

2019-10-09

## Improvements

- Add API parameters and CLI argument for displaying the real-world date and time (potentially inaccurate) (#110, #118)
- Add printer-friendly theme (white background) (#114)

## Documentation

- Add documentation of GIN URLs for public and private repos (#113)

### 1.11.9 neurotic 1.0.0

2019-07-27

First stable release!

## Improvements

- Major API changes (#104, #100, #106)
  - In preparation for this stable release, many formerly public classes and functions were made private. This was done to minimize the number of public classes/functions, which beginning with this release will be treated as stable APIs that are ideally modified only in backwards compatible ways. Users should trust that public classes and functions will not be changed without good reason and a major version bump.
- Many improvements to the documentation, including the addition of an [API Reference Guide](#)
- Add example Jupyter notebook and command line argument for launching it (#108)
- Add file overwrite option to download functions (#106)
- Reserve the metadata keyword `neurotic_config` for global parameters (#93)
  - The `remote_data_root` key must now be nested under `neurotic_config`.

## Bug fixes

- Fix crash when epoch encoder file contains labels not listed in metadata (#97)
- Allow amplitude discriminators to be specified with arbitrary units (#99)

### 1.11.10 neurotic 0.7.0

2019-07-21

## Improvements

- New documentation hosted at Read the Docs: <https://neurotic.readthedocs.io>
- Add menu action for opening metadata in editor (#83)
- Add menu action for opening the selected data directory (#84)
- Add list of installed versions of dependencies and doc links to About window (#44, #65)

## Bug fixes

- Fix files remaining locked after closing a fast-loaded window (#69)
- Fix launching from command line with bad metadata argument (#82)

### 1.11.11 neurotic 0.6.0

2019-07-10

## Improvements

- Add a basic “About neurotic” window with version and website information (#38)
- Update logo (#39)
- Add keywords and project URLs to package metadata (#40)

### 1.11.12 neurotic 0.5.1

2019-07-09

## Compatibility updates

- Compatibility update for RawIOs with non-zero offset (#37)

### 1.11.13 neurotic 0.5.0

2019-07-06

## Improvements

- Support fast (lazy) loading in Neo < 0.8.0 (#35)
- Add “git.” and conditionally “.dirty” to dev local version identifier (#34)

### 1.11.14 neurotic 0.4.2

2019-07-06

## Bug fixes

- Fix for EstimateVideoJumpTimes regression introduced in 0.4.0 (#33)

### 1.11.15 neurotic 0.4.1

2019-07-02

## Compatibility updates

- Change sources of development versions of dependencies (#32)
- Compatibility update for scaling of raw signals (#31)

### 1.11.16 neurotic 0.4.0

2019-07-01

## Improvements

- Show epochs imported from CSV files with zero duration in epoch viewer (#27)
- Show epochs/events imported from data file in events list/epoch viewer (#28)
- Alphabetize epoch and event channels by name (#29)

### 1.11.17 neurotic 0.3.0

2019-06-29

## Improvements

- Remove dependency on ipywidgets by making notebook widgets optional (#25)
  - Notebook widget classes renamed: `MetadataSelector` → `MetadataSelectorWidget`, `EphyviewerConfigurator` → `EphyviewerConfiguratorWidget`
- Add app description and screenshot to README (#22)
- Promote to beta status (#23)

### 1.11.18 neurotic 0.2.0

2019-06-28

## Improvements

- Add basic command line arguments (#14)
- Add continuous integration with Travis CI for automated testing (#13)
- Add some tests (#15, #16)
- Migrate example data to GIN (#18)

## Bug fixes

- Fix crash when downloading from a server that does not report file size (#17)
- Raise an exception if a Neo RawIO cannot be found for the data file (#12)

### 1.11.19 neurotic 0.1.1

2019-06-22

## Bug fixes

- Fix various downloader errors (#7)

### 1.11.20 neurotic 0.1.0

2019-06-22

- First release
